PREFACE

Staff papers present reports on BEA research that is more specialized or less well established than BEA research generally made available to the public.

The work for this paper was performed in the Interindustry Economics Division under the guidance of Philip M. Ritz, Chief. Paula C. Young, Chief of the Input-Output Structures Branch, was in direct charge of the study, with important assistance provided by Shirley F. Loftus, Myles Levin, and Kevin D. Ryan. Elizabeth G. Rhodes and Karen D. Redman provided statistical assistance. Camera-ready copy was prepared by Peggy L. Burcham.

16. Abstracts

Provides input-output tables for 1972 at the 85-industry level, based on application of update procedures to the revised 1967 benchmark input-output table. Included is a comparison of actual industry outputs (in 1967 dollars) for 1972 with outputs generated by multiplying 1972 final demand estimates (in 1967 dollars) by the coefficients in the revised 1967 total requirements table.

Also provided are transactions and direct requirements tables for 1972 stated in 1967 dollars.

UPDATED INPUT-OUTPUT TABLE OF THE U.S. ECONOMY: 1972
(DERIVED FROM THE 1967 INPUT-OUTPUT TABLE)

This report presents an 85-industry input-output (I-O) table of the U.S. economy for 1972, obtained by updating BEA's benchmark I-O table for 1967. 1/ It also includes a comparison of estimates of actual industry output for 1972 with output derived by using the 1967 I-O coefficients and the estimates of final demand for 1972 in this study. 2/ This comparison supports the usefulness of updated tables for years when benchmark tables are not available.

The updated I-O tables for 1972 are shown in both current dollars and constant (1967) dollars. Current-dollar estimates of transactions, direct requirements per dollar of output (i.e., input coefficients), and total requirements per dollar of delivery to final demand (i.e., total requirements or inverse coefficients) are shown in tables 1, 2, and 3, respectively. Transactions and direct requirements in 1967 dollars are shown in tables 4 and 5, respectively. A constant-dollar total requirements table was not prepared.

---

1. This table has been updated from the revised version of the 1967 I-O table, which incorporated the changes in the national income and product accounts (NIPA's) presented in the SURVEY OF CURRENT BUSINESS, January 1976. The revised 1967 I-O table was published in June 1977 as BEA Staff Paper No. 29. Copies may be secured from the National Technical Information Service (NTIS), Springfield, Virginia 22161, at $5.25 per copy ($3.00 in microfiche). The accession number is PB-270-259/AS.

2. The estimates of 1972 GNP and its final demand components in the 1972 updated I-O table are based on the results of the 1972 full-scale benchmark I-O study (scheduled for release shortly). They differ from those currently published in the NIPA's. GNP is $11.6 billion higher than in the NIPA's, resulting from estimates which are $5.0 billion higher for personal consumption expenditures, $6.1 billion higher for gross private fixed capital formation, $0.9 billion higher for change in business inventories, $0.1 billion lower for net exports, and $0.3 billion lower for government purchases of goods and services.

NOTE: Copies of the updated I-O tables for 1968, 1969, and 1970 (BEA Staff Paper No. 27) and the table for 1971 (BEA Staff Paper No. 28) may be secured from NTIS, at $6.00 per copy for Staff Paper No. 27 and $4.50 for No. 28. Both are available in microfiche, at $3.00 apiece. The accession numbers are PB-246-690 and PB-265-194, respectively.

Updated versions of the 1958 I-O table to 1961 and of the 1963 table to 1966 were prepared by BEA. The 1961 table was published in *Input-Output Transactions: 1961*, Staff Working Paper in Economics and Statistics, No. 16, Office of Business Economics (now BEA), July 1968. Copies of this paper may be secured from the Interindustry Economics Division (IED). The 1966 table appeared in *Input-Output Transactions: 1966*, Staff Working Paper in Economics and Statistics, No. 19, BEA. This is available only from NTIS, at $4.50 per copy and $3.00 in microfiche, accession number COM 72-10299.

A discussion of the characteristics and uses of BEA's I-O tables appears in *The Input-Output Structure of the U.S. Economy: 1967*, in the February 1974 SURVEY OF CURRENT BUSINESS. Single copies of the reprint may be secured from IED.

Unlike updated tables for earlier years, the 1972 updated I-O table incorporates estimates of final demand that are based on the results of a full-scale benchmark I-O table for the year under study. An important advantage of this approach is that it permits an evaluation of the average change in input requirements for each industry from 1967 to 1972 based on benchmark measures of final demand, that is, it abstracts from errors in summary extrapolations of final demand. Furthermore, when the 1972 benchmark table and the 1972 updated table are put in comparable industry classification, it will be possible to evaluate the updating procedure in detail by comparing individual input coefficients in the updated table with those in the benchmark table.

Differences in Output Requirements, 1967 to 1972

The extent to which the I-O relationships have changed since 1967 can be evaluated by comparing the estimates of actual industry output for 1972 (in 1967 dollars) with derived industry output obtained by multiplying the final demand estimates for 1972 (in 1967 dollars) by the 1967 total requirements per dollar of delivery to final demand, based on the revised 1967 I-O table. The derived output represents the output that would have been required by the 1967 I-O relationships to supply the sales to final demand for 1972. The derived output less the actual output for each industry is expressed as a percentage of actual output and converted to average annual rates of change from 1967. The actual industry outputs, the differences between derived and actual output, and the average annual rates are shown in table A.

The difference between derived and actual output (average annual rate) for most industries falls within a narrow range. Differences of 2 percent or less occur in 62 of the 79 I-O industries shown (excluding new construction, for which derived and actual output are always the same). Differences greater than 5 percent appear for only 2 industries: wood containers (I-O 21) and office supplies (I-O 82).

The largest underestimates of actual output are shown by the following industries: plastics and synthetic materials (I-O 28); rubber and miscellaneous plastics products (I-O 32); and service industry machines (I-O 52). The largest overestimates are shown by the following industries: forestry and fishery products (I-O 3); coal mining (I-O 7); wood containers (I-O 21); leather tanning and industrial leather products (I-O 33); metalworking machinery and equipment (I-O 47); machine shop products (I-O 50); and office supplies (I-O 82). These results are generally consistent with past changes in the requirements for the products of these industries.

The difference between derived and actual requirements points up the need for users of I-O to take into account the fact that I-O coefficients do change, even over relatively short periods. Among the factors that cause coefficient change are: (1) changes in technology, which may reflect use of new machinery, new material inputs, expenditures for pollution abatement, etc.; (2) changes in the mix of the products included within an industry's output when each of the products requires a different pattern of inputs; (3) changes in relative prices, which may lead an industry to substitute one input for another if the substitute becomes relatively less expensive or to use less of an increasingly costly input; and (4) variations in the scale of operation, which would affect certain inputs, such as rent and building maintenance, that may not change proportionately with a change in output. With regard to the last, the study shows a generally increasing trend in the use of services, indicating that changes in technology and organization remain important.

As the annual series of updated I-O tables are extended, they provide a better basis for further study of coefficient change and for adjustment of the coefficients to account for such changes in applications of I-O techniques. 3/

Information useful for such adjustments appears in table B, which shows the percentage difference (at annual average rates) between derived and actual industry output for each year from 1968 to 1972. These percentages reveal whether or not there has been a consistent pattern over these years in the amount and direction of the differences between derived and actual output. For example, the derived output overestimated actual output in 34 of the 79 industries shown for at least 4 of the 5 years, including 25 industries for all 5 years. Correspondingly, underestimates of actual output occurred in 29 industries for at least 4 years, including 20 industries for all 5 years. However, it can be seen that in many industries, while the direction of the difference has been consistent, the amount of the difference has varied considerably.

Methods Used to Update I-O Data

The updated tables for years between the quinquennial economic censuses must be based on summary estimating methods because much less data are available for these years. For the 1972 updated table, the estimates of industry output and of final demand were based on the benchmark I-O study for 1972. However, the interindustry relationships for the 1972 updated table are derived from the revised 1967 benchmark table and, in general, incorporate allowances for only the average change from 1967 to 1972 in the use of a product or service among industries. A description of the methods follows:

1. GNP and components

   The estimates for each final demand component are based on estimates prepared for the benchmark I-O table for 1972, which are adjusted to the classifications and conventions used in the 1967 benchmark I-O table. That is, the industry classification in the updated table for 1972 is based on the 1967 Standard Industrial Classification (SIC), whereas the benchmark table for 1972 uses the 1972 SIC. Furthermore, the conventions in the 1972 updated table (for example, the treatment of secondary products) are the same as those in the 1967 benchmark table, rather than those in the 1972 benchmark table.

2. Industry output totals and the adjustment of intermediate flows 4/

   The next step is the calculation of industry output totals and the updating of the base year (1967) table to reflect 1972 levels of production, product mix, and prices. For this purpose, it is necessary to use the most detailed 1967 I-O transactions table available. This table classifies the economy into 484 separate industries.

---

3. A discussion of similar considerations, based on I-O tables for earlier years, appears in BEA Staff Paper No. 26, *Sources of Error in Input-Output Projections*, by Arlene K. Shapiro, July 1975, available from NTIS, accession number COM 75-11074/AS, at $4.50 for paper and $3.00 in microfiche.

4. Intermediate flows in the I-O table are those which represent transactions among industries. Excluded are value added inputs and flows to final demand.

Output totals for each industry for 1972 are based on the estimates made for the 1972 benchmark I-O study. The output totals are adjusted to fit the 1967 industry classification and definitions and then deflated to 1967 prices. Ratios are calculated of the value of output for 1972 in 1967 prices to the value of output for 1967. The estimates in the 484-industry I-O transactions table for 1967 are adjusted to exclude transfers of secondary products of the producing industry, leaving only the primary transactions flows. 5/ The primary flows in each cell of each column of the 1967 table (excluding value added) are multiplied by the 1972/1967 output ratio to give the initial input estimates for 1972 in 1967 prices, for each of the 484 industries.

The estimate in each cell is adjusted to reflect 1972 prices. For this adjustment, the flows from an industry to each of its consumers are multiplied by special price indexes representing the change in the price of the particular composite of goods and services included in the flow to the specific consuming industry.

Sources for the price indexes include the Bureau of Labor Statistics (BLS) *Wholesale Price Index* and *Consumer Price Index*, and price data from the Department of Agriculture, Bureau of Mines, etc. For those cases where there is no price index directly applicable to a given item, a price index is developed either from selected wholesale price indexes for related commodities or from cost indexes based on costs of labor and materials inputs.

The data are then aggregated to the 85-industry level. Value added for each industry is derived by subtracting the sum of the adjusted intermediate inputs of an industry from the actual 1972 output for that industry.

3. Balancing the table

The final step in deriving the updated 1972 I-O table involves adjusting the intermediate portion of the table. For this step, the 1972 sales to final demand by industry noted in step 1 are subtracted from the actual 1972 output to derive the initial estimates of the 1972 intermediate sales. The estimates of intermediate sales are compared with the estimates of such sales derived in step 2. Large differences are investigated and changes are made where warranted. Remaining differences are eliminated by proportionately adjusted the intermediate sales of that industry to the purchasing (consuming) industries.

5. In general, secondary production of an industry was treated as if sold by the producing industry to the industry which was the primary producer of that product. Primary flows are those which represent actual transactions; i.e., the distribution of products and services from the primary producing industry to the using industry. For a more complete discussion of secondary products, see the article in the February 1974 SURVEY.

At this point, the adjusted table consists of the flows of primary products only. Estimates of each industry's production of secondary products are calculated using the secondary product transfers from the 1967 I-O table, adjusted to reflect the change in primary product output from 1967 to 1972. In addition, data for transferred imports are developed from the Census Bureau's foreign trade statistics for 1972.

The estimates of both secondary output and transferred imports are added to the primary flow table to yield the conventional I-O transactions table for 1972 (table 1), and the direct requirements and total requirements table (tables 2 and 3, respectively) are calculated therefrom.

Updated I-O Tables for 1972 in 1967 Dollars

Tables 4 and 5 show 1972 transactions and direct requirements coefficients in 1967 dollars. The deflators used to calculate the intermediate portion of table 4 were those used in the preparation of the intermediate portion of table 1. The final demand estimates in table 4 were calculated by deflating 1972 final demand, using deflators prepared at the 484-industry level and applied to the individual 484-industry components of each 85-industry sale to a final demand category. Value added was developed residually for each 85-order industry. Table 5 was calculated from the data in table 4 by dividing each industry's intermediate inputs and value added by the industry's total output.

1/ Derived output based on use of 1967 coefficients.
2/ See table A for titles.
3/ Rate not shown because it is not comparable with rates for other years as a result of revised treatment of privately administered workmen's compensation funds introduced in the January 1976 NIPA benchmark revision.
* Less than ± .05 percent.

TABLES 1 and 4

*Less than $500,000.
Detail may not add to total due to rounding.

In row TR, the entry in each column represents the sum of the values of transferred imports at domestic port value and the value of the secondary output of other industries which has been transferred to the industry named at the head of the column.

In column 94, the detailed entries reflect gross exports of goods and services from each producing industry. Imports in total are shown as negative entries in this column on rows 80A and 80B. Therefore, the sum of the column equals the GNP component "net exports of goods and services."

In column 99.04, the entry in each row represents the value of output of the industry named at the beginning of the row which has been transferred to other industries for distribution. These entries include secondary products which have been transferred to "dummy" industries.

TABLES 2 and 5

*Less than .000005.
Detail may not add to total due to rounding.

To remove a source of instability in the measurement of direct requirements per dollar of output and total requirements per dollar of delivery to final demand, the Commodity Credit Corporation has been excluded from industry 78. The excluded inputs to the CCC from the specified industries for table 2 are: industry 2, $178 million; industry 14, $48 million; industry 65, $368 million; and value added, -$595 million; for table 5 they are: industry 2, $156 million; industry 14, $42 million; industry 65, $307 million; and value added, -$504 million.

TABLE 3

To prevent requirements for scrap and by-products from generating production, scrap and by-products have been treated as inputs to the producing industry rather than to the consuming industry.

Each entry represents the output required, directly and indirectly, from the industry named at the beginning of the row for each dollar of delivery to final demand by the industry named at the head of the column.
